"Performance Analysis of Split-Case Sorting Systems"
by Johnson and Meller

## Main Points

- Split-case sorting system operation and technology.
- Use Bernoulli process to model induction process and characterize negative effect of inductor interference.
- Faster inductors should be placed upstream.
- Split induction systems can outperform side-byside induction systems.
- Presorting can be used for increased throughput (but it can hurt picking).
"Performance Analysis of Split-Case Sorting Systems"
by Johnson and Meller

## Introduction

- Used in order fulfillment centers (e.g., Amazon.com, L. L. Bean, or Sears).
- Need to fill lots of orders with common items.
- Can either go out and pick each order individually (stopping at the same location multiple times) or pick a batch of orders at a time and then sort them into individual orders.
- When order commonality is high enough, then batch picking of full cases and splitting the cases for sorting is efficient.

## Automated Sorting System

conveyor
from picking area

## Sorting Systemes subs systens

- Induction:
- typically manual (humans)
- can be automated (robots or conveyors)
- Sortation:
- manual (humans) or
- automated conveyors (tilt-tray, bomb-bay, cross-belt)
- Packing:
- place items into shipping carton
- check for all items (quality assurance)
- add packing slip/invoice
- button up

## Induction Process

- Paper makes claim that induction process is the critical process/sub-system.
- Tends to limit throughput of the system once sorter hardware is in place.
- Decisions:
- How many inductors?
- Where to place them at stations and within station?
- Objective:
- Would like to minimize cost (function of number of pickers and picking stations).
- Need to meet throughput requirements.

## Notation

- $p_{i}=$ probability that inductor $i$ can induct onto a moving conveyor $(i=1, \ldots, N)$
- $p_{i}=\lambda_{i} / s, \lambda_{i}<s$
- $\lambda_{i}=$ the induction rate of inductor $i$ if working in isolation
- $s=$ speed of the conveyor
- $\lambda_{i}^{\prime}=$ the effective induction rate of inductor $i ; \lambda_{i}^{\prime} \leq \lambda_{i}<s$

## Side-by-Side Inductor Interference

## Side-by-Side Inductors

- $\lambda_{1}^{\prime}=\lambda_{1}$ since inductor 1 is never blocked
- What about inductor 2 ?
- Geometric Distribution ( $p$ ): Mean number of trials until first success equals $1 / p$.
- Mean number of trials until inductor 2 ready to place an item on $=1 / p_{2}-1$.
- Mean number of trials until inductor 2 sees an empty tray $=$ $1 /\left(1-p_{1}\right)$.
- Add these together and take the inverse ... yields the probability that inductor 2 hits the next tray.
- Multiply by $s$ and you have the effective induction rate of inductor 2: $\lambda_{2}^{\prime}=\left[\frac{1}{\lambda_{2} / s}-1+\frac{1}{1-\lambda_{1} / s}\right]^{-1} s$.

## Side-by-Side Inductor Interference

## Faster Inductor

- When one inductor is faster than the other, which inductor should be first?
- Can answer mathematically (see Result 1 ).

## Faster Inductor

## Split Inductors

## Split Inductors

- Now both workers will experience blocking (not just the second inductor).
- Assume that items are equally-likely to be destined for any pack station.
- As a result, $1 / 2$ of the items will be sorted before arriving at the other station.
- $\lambda_{2}^{\prime}=\left[\frac{1}{\lambda_{2} / s}-1+\frac{1}{1-\lambda_{1}^{\prime} /(2 s)}\right]^{-1} s$
- $\lambda_{1}^{\prime}=\left[\frac{1}{\lambda_{1} / s}-1+\frac{1}{1-\lambda_{2}^{\prime} /(2 s)}\right]^{-1} s$
- $\lambda_{1}^{\prime}=\lambda_{2}^{\prime}=\lambda^{\prime} \Rightarrow(3)$
- Result 2 tells us that SPL always does better than $\operatorname{SBS}$ for $\lambda<s$.

## Split Results

Result 2: For two inductors each with nominal induction rate $\lambda$ $(\lambda<s)$, the total effective induction rate of a split system is larger than that of a side-by-side configuration $\left(\Lambda_{S P L}^{\prime}>\Lambda_{S B S}^{\prime}\right)$.

Result 3: For two inductors working in a split configuration with nominal induction rates limited by the conveyor speed (i.e., $\lambda_{i}=s$, $i=1,2)$, the total effective induction rate is expressed as $\Lambda_{S P L}^{\prime}=\left(\frac{4}{3}\right) s$.

Result 4: For $N$ inductors working in an equally spaced split configuration (with $B>N$ evenly distributed between the inductors) with nominal induction rates limited by the conveyor speed (i.e., $\lambda_{i}=s, i=1, \ldots, N$ ), the total effective induction rate is expressed as $\Lambda_{S P L}^{\prime}=\left(\frac{2 N}{N+1}\right) s$. Moreover, $\lim _{N \rightarrow \infty} \Lambda_{S P L}^{\prime}=2 s$.

## Improvement with Split

## Presorting to Improve Sorter Throughput

- With two stations and no presorting:

$$
\lambda^{\prime}=\left[\frac{1}{\lambda / s}-1+\frac{1}{1-\lambda^{\prime} /(2 s)}\right]^{-1} s
$$

- With two stations and presorting that leads to dropoff probability equal to $d(d>0.5)$ :

$$
\lambda^{\prime}=\left[\frac{1}{\lambda / s}-1+\frac{1}{1-(1-d) \lambda^{\prime} / s}\right]^{-1} s
$$

- Note that this improves sorter throughput at the price of decreasing picking throughput.

## Presorting to Improve Sorter Throughput

## Approximate Model for Low Induction Variance

- Motivated by case where inductors found a rhythm.
- Did not see such "random" blocking as model would predict.
- Used an approximate queueing model based on lower bound and upper bound of throughput.
- Lower bound on throughput: Geometric Model.
- Upper bound on throughput: Finite Model.
- See paper for details (pp. 267-269).
- Approximation performed well (see Tables 1-4).

Average (Absolute) \% Error $=0.58 \%$.

## Conclusions

- Concepts:
- When does it pay to split induction stations?
- When does it make sense to presort the items?
- When do you need to use approximate model (with queueing approximation)?
- Skills:
- Calculate the throughput of a side-by-side system with 2 inductors (see pg. 12).
- Calculate the throughput of a split system with 2 inductors (see pg. 12).
- Calculate the maximum throughput of a system with $N$ induction stations.
- Calculate the throughput of a split system with 2 inductors and presorting (see pp. 15-16).
- Extension:
- Alluded to more than two inductors ... how would you modify the models?
